Summary: Based on climate predictions, current conditions, and field observations, the threat for mass coral bleaching within the FKNMS remains LOW.

According to the latest NOAA Coral Reef Watch (CRW) experimental Coral Bleaching Thermal Stress Outlook, there is still high possibility for thermal stress capable of causing coral bleaching throughout the southern Caribbean during the coming months. However, the forecast for the Florida Keys region indicates that there is no significant potential for coral bleaching for the remainder of 2010. (Fig. 1).

Current remote sensing analysis by NOAA’s CRW program indicates that the Florida Keys region is presently experiencing minimal to no thermal stress. NOAA’s recent experimental Coral Bleaching HotSpot Map (Fig.2), which illustrates current sea surface temperatures compared to the average temperature for the warmest month, shows that sea surface temperatures are not elevated for this time of year in the Florida Keys. Similarly, NOAA’s latest experimental Degree Heating Weeks (DHW) map, which shows how much heat stress has built up over the past 12 weeks (Fig.3), illustrates minimal accumulated temperature stress in the Florida Keys. Furthermore, NOAA’s Integrated Coral Observing Network (ICON) monitoring stations, which provide near real time in-situ sea temperature data along the outer reef tract throughout the Florida Keys, confirm that sea temperatures throughout the Florida Keys have been well below 30°C over the past month (Fig. 4) and despite brief periods of calm winds over the past month, there have been no prolonged doldrum-like conditions in the Florida Keys region (Fig. 5). Finally, NOAA’s Coral Reef Watch program continues to maintain a coral bleaching alert status of “No Stress”, indicating that significant coral bleaching is not likely to occur in the Florida Keys for the remainder of 2010. As a result, this will be the final current conditions report for 2010.
Conditions of Corals

A total of eight BleachWatch Observer reports were received during the month of October, with one report indicating only isolated colonies exhibiting signs of paling such as Mound and Boulder and Brain corals. The remaining reports indicated that no significant signs of coral bleaching were observed. At the site where paling was noted (Fig. 7), the overall percentage of corals exhibiting signs of thermal stress ranged from only 1-10% of corals. Other observations included no paling or bleaching on *Palythoa sp.*, fire coral or Gorgonians.

The 2010 BleachWatch season has come to an end with a record total of 226 reports submitted by BleachWatch observers (Fig. 8). Observer reports verified that only minimal signs of coral bleaching were observed in the Florida Keys region in 2010, with most reports noting only paling or partial bleaching. Based on current environmental conditions and the limited number of isolated paling or partially bleached corals noted by BleachWatch observers, significant coral bleaching in the Florida Keys National Marine Sanctuary and surrounding waters seems highly unlikely at this time. As a result, this will be the final current conditions report for 2010.

**BleachWatch Reports for June-October, 2010**
